## How Time Balls Worked

"Excuse me, do you have the time?" asks a person from downtown. "Sure, it is ten past ten o'clock," answers the person from Mt. Healthy. "Oh my, I have twenty past ten o'clock." Immediately, the person from Loveland speaks up to say, "You're both wrong. The time is twenty-eight past ten o'clock." Who is correct and how do you know?

How was time determined in the Greater Cincinnati area before radio signals, telegraphy, or other electronic methods? Perhaps your answer would include a shadow clock or maybe the pendulum clock. The question is how did a clock registering noon on the west side of Cincinnati coincide with a clock registering noon on the east side? Many citizens depended on railway time, but how did they decide the *correct* time? As civilization evolved and industrialization became popular, knowing the correct time both day and night was important.

To help understand the horology question is to look at how time is measured. Rotation of the earth determines our time, and, since about 3,500 BC, as noted by *Clock a History*, the earth's rotation has been acknowledged by observing the shadow position of the sun. The sundial and shadow clock are typical historical examples for determining solar time.

Two tasks, one of measuring the sun's position and one of displaying solar time, are achieved by a shadow clock. Located in front of the Cincinnati Observatory and often demonstrated to visitors by an outreach astronomer, the Planispheric Analemma Sundial can display time of day with a typical accuracy of 20 seconds. Bigger can be better, as demonstrated by the historic Stonehenge, often reported to accurately predict the rising and setting of the sun, moon, and stars.

Precisely positioned brick, stone, and bronze make this Planispheric Analemma Sundial accurate to within 20 seconds and visible to all that visit the observatory. Image by L. Hite

An enigmatic structure appeared suddenly at the Cincinnati Observatory positioned around the Planispheric Analemma Sundial. According to Dean Regas, the Outreach Astronomer and Co-Host of the PBS program *Star Gazers*, it appears to be a recreation of the famous Stonehenge monument except made entirely from boxes. Was it made by a race of Celtic giants? Is it alien in origin? What civilization could've produced such a thing? And for what purpose? Image by Leo Sack, Cincinnati Observatory Center, COC

More accurate for the measurement of the sun's position than a sundial is the telescope. Solar time is noted by an astronomer observing the movement of the sun using a telescope constrained to move only in the plane of the observer's meridian. The telescope relies on the rotation of the earth to bring the sun into its field of view and is mounted on a fixed horizontal east-west axis. A *meridian circle telescope* and a *transit telescope* are descriptive terms associated with these special scopes.

Timekeeping for the Cincinnati area began at the birthplace of American astronomy, The Cincinnati Observatory, located on Mt. Ida in Cincinnati, Ohio. In 1843, Mt. Ida was renamed Mt. Adams after the observatory's cornerstone was laid by John Quincy Adams, former President of the USA.

To begin the process of determining time for the Cincinnati area, Superintendent Dr. A. D. Basche, from the United States Coast Survey, loaned the Mt. Adams Observatory its first transit telescope as noted on page 207 in Charles Cist's Sketches & Statistics of Cincinnati.

Mounted on a stone pier, the Buff & Berger transit telescope was operational from 1885 to 1888. Image from COC

Unlike the shadow clock, Basche's transit telescope did not display time. Instead, using the telescope, an astronomer observed the crossing of the sun at its highest point in the day. That observation of time was synchronized with the observatory's public clock donated by Wilson McGrew of Cincinnati. Mr. Twitchell, assistant to Professor Ormsby M. Mitchel, began regulating McGrew's Standard Public Clock in 1850, as mentioned on page 18 in the Proceedings of The American Metrological Society. Eventually this clock was upgraded to a Robert Molyneux pendulum clock.

A timekeeping outreach program for the public began when the observatory supplied correct time to four jewelry shops in the city below Mt. Adams, as noted in *Annual Report 2011*, Cincinnati Observatory Center. Citizens brought their pocket watches and other spring-driven clocks to the jewelry shops to find if their clocks were going fast or slow. Beginning in 1868 and under the leadership of Professor Cleveland Abbe, the observatory began regulating time more systematically for all the jewelry shops.

Consistent with many observatories across the country, the Cincinnati astronomical observatory was the only source for exact time in Cincinnati until about 1910. This was not Greenwich Mean Time or Standard Time but Solar Time, or Astronomical Time, or Observatory Time.

Founded in 1842 on Mt. Ida, the observatory was eventually closed because of atmospheric smoke caused by the burning of soft coal. Image from COC

To get away from the downtown pollution caused by the burning of soft coal, the Cincinnati Astronomical Society decided to close the observatory. The society constructed a new observatory, now owned by the University of Cincinnati, five miles east of the city in 1873. This move to Mt. Lookout caused the need for a different method of communicating time to local farmers and the citizens of Cincinnati. Former assistant at the U.S. Naval Observatory and director for the Cincinnati Observatory from 1875 to 1882, Ormond Stone instituted the observatory's time ball in cooperation with the Army Signal Service, as reported in the *American Metrological Society Proceedings*. Used in Cincinnati and around the world, particularly along coast lines, this unique method for signaling correct time expanded the observatory's outreach to the public. A 5-foot diameter wire frame ball made from Bessemer steel and covered with black canvas was mounted to a 60-foot pole attached at the rear of the Cincinnati Observatory as explained in the *Construction and Maintenance of Time Balls*. At exactly noon, anyone with a line of sight to the top of the pole could find the correct time by observing a free-fall drop of the ball.

Signaling noon time from the Mt. Lookout Observatory using the time ball lasted from about 1879 to about 1884. Image from COC.

Precisely 15 minutes before noon, the ball was raised, using a windlass, to half-mast, and, at 5 minutes to noon, the ball was lifted to the top, providing viewers with 15-minute and 5-minute advance notices. At astronomical noon in Cincinnati, the ball dropped free-fall style. A hand-operated Prony friction brake allowed the ball to stop gently before the end of its 30-foot travel.

In a handwritten letter from Julius Dexter to A. J. Goshom, dated 16 December 1870 and reprinted in *Chairman of Special Committee of the Common Council of Cincinnati on Standard Public Time*, the observatory sold time to downtown Cincinnati from 1877 to October 1882 for a payment of \$1,000 per year.

Synchronized with the observatory's clock, the new City Clock was destined for Fountain Square in downtown Cincinnati as the official city timepiece. Due to a misunderstanding with the telegraph company, this program was not implemented, and, instead of being installed on Fountain Square, the clock landed in a convenient and conspicuous position on the corner of the Carlisle Building, which was at Fourth and Walnut Streets. (See page 8 of *The Cincinnati Enquirer*.)

The Carlisle Building, located at the corner of Fourth and Walnut Streets, featured a time ball and an outdoor clock, both synchronized with the observatory. Image from The Greater Cincinnati Memory Project and the Public Library of Cincinnati.

Encased in an attractive galvanized iron housing ornately designed by the prominent Cincinnati architect for the Carlisle Building, Albert C. Nash, this gas illuminated Ritchie & Son clock from Edinburgh, Scotland, became the city timepiece. The iron enclosure was funded by Sarah B. Carlisle, owner of the Carlisle Building.

Reported on page 12 of *The Cincinnati Commercial* for April 29, 1877, "The details harmonized well in the way of pilasters, belt courses, panels, ornaments, balconies and general proportions in connection with the main building." Support for the 15-foot high clock housing was from a 5-foot-square turret mounted at the beginning of the fourth floor.

*The Cincinnati Commercial* added that this clock and a companion Ritchie & Son master clock for the observatory cost the city of Cincinnati \$2,500.

The Kilgour family, owners of the telephone company (See *Cincinnati Views*.), donated lines for transmitting time signals from the observatory to the downtown clock, as well as the free use of a telephone and telegraph at the observatory, as

explained in Charles H. Woodward's dissertation, "The History of the Cincinnati Observatory Since 1870." Ormond Stone proclaimed that anyone was welcome to connect lines to the observatory line and that he enjoyed the free telephone privileges.

Professor Smyth was responsible for installing the time ball on top of Nelson's Monument in Edinburgh, Scotland, in 1853. Image from [Edin Photo](#)

Clock construction was supervised by Professor Charles P. Smyth of the Royal Observatory in Edinburgh, Scotland, and, upon completion, the clock was set up, thoroughly tested by him and his assistants, and pronounced a perfect time-keeper. A set of wires, using the Jones method of signaling, connected the City Clock with the clock at the Cincinnati Observatory so the beating of the two clocks was simultaneous. The Ritchie & Son clock, therefore, indicated exact time for the city of Cincinnati.

A time ball was arranged to drop from the top of the Carlisle Building beginning July 18, 1881, as noted on

Clocks manufactured by James Ritchie & Son, Edinburgh, Scotland, were acquired with one clock for the Carlisle Building and a second clock as an upgrade to the observatory's master clock in 1873. Photo by L. Hite

page 66 of the *Ohio Chamber of Commerce and Merchant's Exchange*.

According to page 19 in *Construction and Maintenance of Time Balls*, the 3-foot diameter wire frame ball was mounted to a 30-foot pole and dropped 15 feet at noon. Repeated communication-transmission problems between the observatory in Mt. Lookout and the Carlisle Building caused the ball not always to drop on time. Duhme & Co. jewelry shop paid for the construction and operational of the time ball apparatus while Mr. Carlisle paid for the cost of building the time ball.

Unfortunately, this time ball service to the citizens of Cincinnati was short lived, lasting only 15 months. The telephone company, in accordance with the vote from the Board of Directors of the University of Cincinnati and the operator of the observatory at their meeting in September 1882, removed the telephone from the observatory.

The phone company then refused to transmit further time signals over their line without the presence of a telephone in the observatory. As explained on page 22 in the *Annual Report of the Directors*, no satisfactory arrangements resulted from this decision, and, on 6 October 1882, the president of the Telephone Company removed the line that transmitted a time signal between the observatory and downtown.

By removing the telephone line that transmitted the synchronized time signal from the observatory to the Carlisle Building and to the Central Fire Alarm Office downtown, the city of Cincinnati no longer enjoyed accurate time.

This telegraphy activated fire and time bell sounded at the Milwaukee (Wisconsin) Fire Department. Image from [Old Fire Stuff](#)

As a consequence, the city's time became irregular. When there had seldom been an error of more than one or two seconds, the noon fire bells for the first professional fire department in the United States were often two or three minutes in error! The dropping of the time ball on the Carlisle Building ceased; however, the Ritchie & Son clock on the same building continued to keep excellent time. The large iron enclosure built around the clock in 1877 so reduced the effect of temperature upon the rate of the clock that it was possible to predict its error within less than a second over a span of 10 days. The clock remained in operation until 1913, when it was transferred to City Hall.

Because the University of Cincinnati would not allow a telephone at the observatory, the noon fire bell at the Central Fire Alarm Office for the fire department failed to ring on time. Image from [Cincinnati Views](#)

Telegraphy problems between an observatory and a remote time ball were somewhat common. When communications failed, typically a red flag flew atop the time ball pole to announce no time mark today. If for some reason the noon signal from Washington, D.C., was not received at the Western Union Building in New York, a red flag was raised and flown from 12:01 until 12:10, as noted by *Inside the Apple*.

Occasionally a time ball would drop a few seconds late, and, when this occurred, the ball was again raised and lowered for the same number of seconds it was tardy.

Invented in 1819 by Captain Robert Wauchope, a British Admiral, and reported in *A short Narrative of God's Merciful Dealings*, the concept of the time ball was to save a ship's navigator, often the captain, from coming ashore to set a chronometer. (See the *One o'Clock Gun & Time Ball Association*.) Knowing the exact time is critical to establishing exact longitude. As explained in The "American Method," any location on earth can be mapped by knowing the longitude and latitude of the observer. Because the earth rotates 15 degrees of longitude per hour, the E-W position can be determined by a chronometer, and the determination of latitude, the N-S position, can be made by using a sextant to measure a star's position.

The red flag indicated no time ball today on the Western Union Building in New York. Image from *Inside the Apple*

This is the Western Union finned time ball mounted on the Equitable Life Insurance building in New York. Image from Western Union Time Ball

First erected at Portsmouth, England, in 1829, an experimental time ball station was set up using two balls, one fixed at pole top and one droppable, as mentioned on page 5 in Marking Modern Times in Urban America. The expectation was that an observer on board a rolling ship might be unable to decide if a single ball had fallen but could decide if two balls had separated. The lower ball dropped at precisely noon. The top ball was removed after learning an observer could accurately identify when the lower ball dropped.

Here may be seen the original time ball design by Captain Robert Wauchope. Image from Maritime Time Signals Collection

Not always a ball and not always smooth were alternate shapes used by some observatories. Light weight was a

concern for some and accomplished with semicircular fins made from thin copper sheets and placed about a central axis. Viewed from a distance, the finned structure appeared as a round ball and was easier to lift than the metal clad ball.

Other observatories selected a lightweight ball-shaped basket frame to reduce the dropping weight and wind resistance. Additional shapes included a cylinder, a cone, and a vertical disk.

Eliminating the dropping mechanism was important to other observatories and easily accomplished using a time flap. A thin round metal disk, often with lightening holes, rotated from the vertical position to the horizontal position at the designated time mark. From a distance, an observer easily saw the ball shape disappear and thereby received the intended time signal from the observatory. Most often, two flaps, one in the N-S direction and the other in the E-W direction, assured visibility from all directions.

The first time ball signaling of solar time began at the Greenwich Observatory in England in 1833.

Global time, known as Greenwich Mean Time (GMT), was not used as a worldwide standard until 1954 and is known as *sidereal* (from a Latin word for *star*) time based on stellar observations, not solar time.

Here is a time ball with basket shape at Gdansk, Poland. Image from [Wikipedia](#)

Here is the first U.S. time ball at the Naval Observatory in Washington, D.C., in 1845. Image from [U.S. Navy](#)

The first time ball in the United States was established at the U.S. Naval Observatory in Washington, D.C., about 1845, as reported in [Timekeeping at the U.S. Naval Observatory](#). The ball attached to a flagstaff atop the 9.6-inch telescope dome perched on a bluff above the Potomac River. (See [A Brief History of the Naval Observatory](#).) Released by hand, the ball dropped on the observatory's dome and rolled to the roof below, where it was hoisted by hand to pole top the

next day. The observatory's time ball was upgraded and relocated to the State, War, and Navy Department Building in 1885 and was last dropped in 1936.

This illustration depicts time flaps at the Rotterdam AS Meteor Institute. Image from [Etsy](#)

Before 1883, there was no standard time in the United States, but, in the late 1800s, many major cities had time balls. At noon, people looked up from their work to see the ball drop and check their watches for accuracy. Everybody wanted to be “on time,” and the time ball was a signal that a town could depend on.

Jewelers synchronized small-sized time balls in their display windows with their local observatory causing the ball to drop at noon, signaling solar noon in that city. (See page 6 in [Marking Modern Times in Urban America](#).)

A miniature time ball in an Albany, New York, jewelry shop window, and connected to the Dudley Observatory, was the city’s public time signal from 1861 until 1867. Between 1863 and 1867, the Detroit Observatory, which received time signals from the University of Michigan, Ann Arbor, sent a signal to a miniature time ball in a jeweler’s window in Detroit.

Often jewelry stores displayed an electric clock outside their doors, each store claiming to have the correct time. Observatories sold their time to various organizations such as railway systems and jewelry stores.

Time balls require a line of sight to be effective, but a time gun does not. Not as accurate as a time ball unless the observer could see the gun smoke, a time gun was appreciated by those lacking time ball visibility. Five seconds will pass before the sound from a time gun travels one mile, and an observer at a distance of 5 miles will receive the time mark 25 seconds late. Correction tables were provided to surrounding towns that detailed the expected delay from the gun shot and thereby allowed citizens to set time accurately. Time guns were widely adopted around the world but not often in the United States.

During the 1860s and 1870s, as the railway system expanded, trains were traveling through 49 city-centered solar time zones. For example, depots with more than one railroad passing through typically had a clock for each railway system, such as the depot in Kansas City, Missouri, with five clocks for its five railroad times. Consequently, depots had difficulty keeping their schedules on time, and that resulted in accidents and loss of life.

A miniature remote-controlled time ball ornaments a jewelry shop window. Image from [TYWKIWDBI](#)

The Cape Town, South Africa, noon time gun fires daily. Image from [Cannon Association of South Africa](#)

Railways then began purchasing time from astronomical observatories in selected cities. As taught by the largest telegraphy school in the western hemisphere, The Dodge Institute of Telegraphy in Valparaiso, Indiana, OST, Observatory Standard Time, was the only standard time recognized by a railway line. At 11:00 a.m. daily, OST was telegraphed to all points on the railway. (See page 107 through 108 in *The Telegraph Instructor* by George M. Dodge.) In the Midwest, RST, Railway Standard Time, referred to as CST, Central Standard Time, set the station Railway Standard Clock.

All engineers and conductors carried watches certified by railway time inspectors. Prior to starting a trip, conductors and engineers registered their names and the time after comparing their watches to the telegraph office station clock as required by the railway company.

In the late 1860s, Western Union synchronized designated clocks in principal cities by telegraph with the U.S. Naval Observatory. Eventually this practice spread across the country and became known as Western Union Time.

Railway companies established four provisional time zones in 18 November 1883 to coordinate their train schedules: hence Standard Railway Time. Eventually, railway companies petitioned Congress, which passed the Standard Time Act in 1918 to make railway time zones into law for all of us, as noted in *This Day in History*.

Long after passage of the 1918 Standard Time Law, Cincinnati remained one of the few places in the country where most citizens obstinately refused to use standard time. (See page 9 in *Time Balls: Marking Modern Times in Urban America*.) Instead, many Cincinnatians kept local solar time while others used only railway time.

The Standard Time Act did not solve all the issues with train schedules. For example, Jim Tripp, a telegrapher at the Grand Trunk RR Station in Valparaiso, Indiana between 1960 and 1963, says, "The interesting things at Valpo were issues with time zones. Our train schedules were always in Central Standard Time, even in the summer. Valpo is close to Michigan, which is on Eastern Time, either Daylight or Standard, and it is also close to Illinois, which is on Central Time. It got to the point that, if someone called to ask when a certain train arrived, I would always ask first, what time do you currently have, and many thought I was being smart with them, but I needed to convert their local time to our scheduled time."

Western Union Time was placed in synchronicity with the U.S. Naval Observatory. Image from [Timekeeping at the U.S. Naval Observatory](#)

### Painted Wood Ball

The railway safety signaling system used a ball raised to pole top for a passing train. Image by L. Hite

The railways quickly adopted the concept, known as Ball Signals, of positioning a ball on a pole to communicate safety conditions ahead on the track. At pole top, a white ball indicated a safe condition ahead, and a blocked track was signaled with a black ball showing. Often the engineer would not slow down for a crossing when a white ball was at pole top, and that behavior became known as "highballing a crossing." Red balls were eventually added to the railway signaling protocol to signal danger ahead. As described in *Early Railroad Signals*, beginning in 1869, a ball-shaped structure mounted on a pole and looking like an inverted banjo was named the Banjo Signal. The ball icon remains today a practice used in railroading to communicate a safety condition.

Here is a danger ahead signal at North Conway, New Hampshire. Image from [archlapeer](#)

The 100-day Centennial Exposition of the Ohio Valley and Central States in 1888, held in Washington Park, Cincinnati, featured a William Gardner patented time ball as its central attraction. Located in the Park Building on Elm Street, the time ball was placed on a platform 16 feet high and 8 feet square and erected in the glass-enclosed tower over the main entrance to the Park Building. (See page 63 in the *Centennial Exposition of the Ohio Valley and Central States*.)

Facilitated by the Western Union Telegraph Company, a noon time ball dropped and 5 time gongs sounded from a telegraphy trigger signal sent by the U.S. Naval Observatory in Washington, D.C.

As explained on pages 227 through 232 in the *Annual Reports of the Navy Department*, opening ceremonies for the 1888 Exposition featured a time gong temporarily placed on the stage at Music Hall in Cincinnati. Triggering the gong was a telegraphy signal sent from Nashville, Tennessee, by Mrs. James K. Polk, wife of the former President of the United States.

William F. Gardner was the leading instrument maker for the U.S. Naval Observatory, and five Gardner clocks showing Intercolonial (sixtieth meridian), Eastern, Central, Mountain, and Pacific Coast Time, respectively, were kept running continually and corrected daily by the noon signal from the Naval Observatory.

A time ball was the central attraction of the Park Building on Elm Street. Image from [Official Guide of the Centennial Exposition](#)

To continue providing time to the citizens of Cincinnati from downtown, Shillito's Department Store in Cincinnati began using an Audichron talking clock in 1939, as reported by John Ventre. The device transmitted time to Cincinnatians via the telephone. Customers telephoned Parkway 1700, and a woman's voice gave a short advertisement for Shillito's before telling the time, hour, and minute. The telephone time service (plus weather) still functions today, sponsored by Cincinnati Bell. Give it a try by calling (513) 721-1700.

An Audichron talking clock announced the time, hour, and minute. Image from [Wikipedia](#)

The 167-year-old Robert Molyneux pendulum clock kept time for the city of

The first weather service in the USA was formed at the Cincinnati Observatory on 1 September 1869. Professor Cleveland Abbe, director of the observatory, telegraphed western points to get weather readings, and he noticed that similar weather showed up in Cincinnati two or three days later. Abbe published a weather bulletin of the Cincinnati Observatory that included trial 24-hour weather forecasts. Eventually, the network grew to more than 17 stations located mostly west and south of Cincinnati before merging with the Signal Service network in 1870. Washington, D.C., took notice and asked Abbe to start the National Weather Service!

As an important detail in the history of the time ball, the copper-clad ball in Sidney, Australia, weighs over 265 pounds and is cushioned at the end of its fall by a soapy water shock absorber. An opening in the side of the ball allows a small person to enter and sit on a tiny wooden seat inside the ball, as reported in this video: [Sydney's Secrets](#). Imagine the thrill experienced from the two-meter free fall before hitting the absorber!

## The Going Time at the Observatory

Beginning in 1847, Professor Ormsby M. Mitchel purchased a transit instrument for determining solar time at the observatory. (See the *Three-Inch Transit of the Cincinnati Observatory*.) Mean solar time at the Cincinnati Observatory was eventually determined by a 3-inch transit telescope, in use by 29 July 1878 and made by Buff & Berger from Boston, Massachusetts. It was synchronized to the Robert Molyneux master clock. The clock was a weight-driven pendulum mechanism manufactured in London during the mid-1840s with a mercury filled temperature compensating pendulum. This clock kept time for the city of Cincinnati from 1848 to 1873.

Mounted on a solid stone pier in the transit room, the clock was free of vibrations from the building. In 1880, a large wooden case, 3 feet 8 inches square on the outside, was built around the clock to prevent sudden changes of temperature and may be seen in the background of the Buff & Berger Transit Telescope picture. The case was constructed with double walls. As reported in *The Cincinnati Observatory, Birthplace of American Astronomy* (2006), a window of 3 panes of 3/8 inch plate glass, with air spaces between the panes, enabled the observer to see the face of the clock and the thermometer hung within, without opening the air-tight case.

The Fauth & Co. Meridian Circle Telescope, located in the transit viewing room, is mounted to cast iron piers and features the Hipp Observatory (slave dial) clock attached to the front left-hand pier. Image from COC

The clock remained at a stable temperature while the observing room that housed the transit telescope followed the temperature outdoors. As the outdoor temperature varied, so did the temperature of the telescope. This practice of always keeping the scope at the outdoor temperature minimized sudden thermal changes for the lens and mechanism.

As the pendulum swung back and forth on the Robert Molyneux clock, a needle attached to the bottom of the pendulum contacted a pool of mercury that opened and closed an electric connection to a sounding device in the transit room; hence clock time was communicated by the click of the sounder to the astronomer viewing the stars through the Buff & Berger telescope.

Occasionally, the astronomer adjusted the clock to match exact solar time observations at the observatory. More often, the astronomer noted the clock was going fast or slow and recorded that error rate in an observatory time log.

Note that to the left of the Buff & Berger stellar Transit Telescope pictured in the viewing room rests a chronograph on the small table. Ormsby M. Mitchel developed probably the first working chronograph for automatically recording the beats of a clock, a necessity for

exact timing observations. The chronograph also served a larger program to automatically transmit time and observational information in “real time” over telegraph wires. (See page 4 in *The American Method of Transits*.)

As reported by the Cincinnati Observatory Center, in 1873, when the observatory moved from Mt. Adams to Mt. Lookout on four acres of land donated by board member John Kilgour, the master clock for the observatory was upgraded to a pendulum clock manufactured by James Ritchie & Son, Edinburgh, Scotland.

In September 1888, an upgrade to the transit telescope was enjoyed by the astronomers following the installation of the Fauth & Co. meridian circle telescope manufactured in Washington, D.C. The telescope was located in the transit viewing room.

The Fauth & Co. Meridian Circle Telescope with the sliding bench is shown prior to shipment from the factory. Image from

The Hipp Observatory (slave dial) clock from Peyer Favarger & Co. was controlled by the Riefler slave clock in the master clock vault and was visible to the astronomer operating the Meridian Circle Telescope.

Photo by L. Hite

An astronomer reclined on a bench, mounted on sliding rails, under the eyepiece for the telescope and observed the crossing of the sun at its highest point in the day. That observation of time was then synchronized with a Hipp Observatory (slave dial) clock from Peyer Favarger & Co., Neuchatel, Switzerland, mounted on the meridian telescope. The slave dial clock was synchronized with the master clock.

Between 1904 and 1906, electricity was installed at the observatory. The master clock was again upgraded in 1909 using the system of Riefler

pendulum clocks, accurate to about 10 milliseconds per day. The Riefler master tank clock, SN 225, and the Riefler slave cabinet clock, SN 212, are pictured later in the photo gallery and are located in a temperature-stabilized vault in the basement of the observatory. Pages 344 through 351 in *Popular Astronomy*, Vol. XIX (1911), reported that wood was not used in the construction for the glass-enclosed clock made in Germany by Clemens Riefler, thereby eliminating expansion or contraction of clock parts caused by the presence of moisture.

Located in the master clock vault, the Riefler clock system comprised the slave cabinet clock and the master tank clock with the attached hand-operated air/vacuum pump. Image from Clock Systems of the Cincinnati Observatory

Corrections to the slave clock used the traditional pendulum length adjustment; however, corrections to the Riefler tank master clock required adding or removing air on the inside of the sealed glass tank using a hand air/vacuum pump.

Looking through a double glass viewing window into the clock vault, the astronomer observed both the master clock and the slave clock without entering the room. Every 35 to 40 seconds, the master clock battery-powered winding mechanism activated. An occasional visit to the inside of the vault was necessary to adjust the air pressure in the glass-enclosed master clock or to change batteries.

Master clock time was communicated to the astronomer, upstairs in the transit viewing room, using the slave clock in the vault. The slave clock was synchronized to the Hipp Observatory (slave dial) clock mounted on the support pier for the meridian circle telescope. This arrangement allowed for convenient viewing of the master clock time by the astronomer.

The Western Electric Company 1.5 Volt carbon battery was a typical power source for the Riefler clock system. (See the [photo gallery](#).)

Solar time is measured by the apparent diurnal motion of the sun. Cincinnati noon in solar time is the moment when the sun is at its highest point in the sky (exactly due south or north depending on the observer's latitude and the season). The average time taken for the sun to return to its highest point is 24 hours. When the observatory moved from Mt. Adams to Mt. Lookout, OST was 19.1 seconds later.

A sidereal day is about 23 hours, 56 minutes, 4.091 seconds, corresponding to the time it takes for the earth to complete one rotation relative to the vernal equinox. During the time needed by the earth to complete a rotation around its axis (a sidereal day), the earth moves a short distance (approximately  $1^\circ$ ) along its orbit around the sun; therefore, after a sidereal day, the earth still needs to rotate a small extra angular distance before the sun reaches its highest point. A solar day is nearly 4 minutes longer than a sidereal day.

Leap year is based on the sidereal year, the period that it takes the earth to orbit (revolve around the sun) in reference to a distant star. The period is 365.25636 days; hence, every four years, the earth's place in reference to the first point of Aries is off by one day, which is the ascending node of the intersection of the celestial equator and the ecliptic. To keep the astronomical year in sync with the calendar year, an extra day is necessary on 29 February every four years, with a few exceptions on the century years.

Historian and former director of the Cincinnati Observatory Center, John Ventre demonstrates to a group of visiting engineers the vintage 1845 Merz and Mahler refractor telescope, located in the Ormsby M. Mitchel building.  
Photo by L. Hite

People govern their daily lives via solar time, and the observatory's telescopes run on sidereal time.

## Acknowledgments

I thank John Ventre, historian and former director of the Cincinnati Observatory Center, for providing valuable details, technical editing, and important documents, along with an enlightening perspective on history.

I thank Dr. Robert T. Rhode for his important assistance with editing. Check his site, [www.roberttrhode.org](http://www.roberttrhode.org), where you find fascinating "Books and eBooks from the HeartLand" and several free documents to enjoy, including original portraits of famous authors painted in the sumi-e tradition, greeting cards, and suggestions for writers.

I thank Klaus Hulse, from Germany, for making available to all of us his wonderful collection of pictures for time balls, time flaps, and time guns. Please see his site at: <http://www.leuchtturm-welt.net/HTML/TIMEBPK/TIMEBALL.HTM> for additional collections of historical pictures.

The Ormsby M. Mitchel building at the Mt. Lookout Observatory is situated next to a circular brick patio featuring wrought iron benches. Photo by L. Hite

## Photo Gallery

*The Riefler & Company Master Tank Clock, mounted on a 3-inch thick marble stone located in the clock vault, is shown with the hand air pump used to evacuate the glass sealed clock chamber.*

Corrections to the Riefler tank master clock required adding or removing air on the inside of the sealed glass tank using a hand air/vacuum pump shown below. Every 35 to 40 seconds, the master clock battery-powered winding mechanism activated.

The Riefler Slave Clock is in the clock vault.

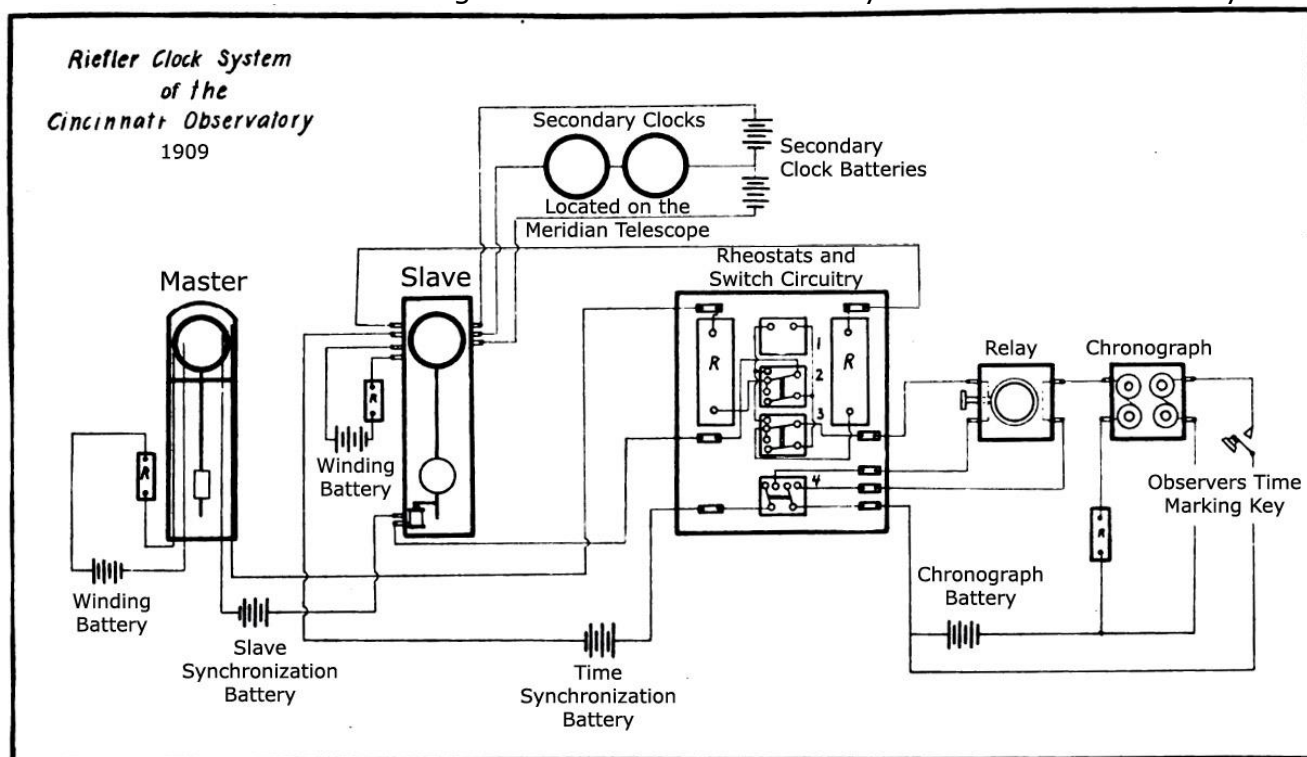

Here is the Riefler Slave Clock battery-powered winding mechanism.

Here is the Schematic diagram for the Riefler Clock System at the Observatory.

The Western Electric Company 1.5 Volt carbon battery shown below was a typical power source for the Riefler clock system pictured beside the battery including the hand operated air/vacuum pump. Also shown is the rheostat used to control current flow to the slave and master clock.

Here is the Warner and Swasey Co. Drum Chronograph made in Cleveland, Ohio.

The transit viewing room is now a classroom. Note the center viewing window in the far wall and in the ceiling.

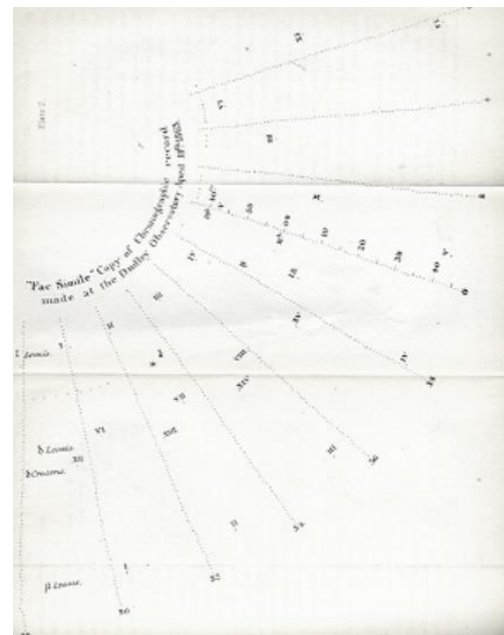

The Buff & Berger transit telescope mounted on a stone pier, the drum chronograph, and the vault for the Robert Molyneux master clock are shown in the transit room below.

The revolving-disk chronograph with its accompanying disk-chart, developed by Ormsby MacKnight Mitchel in 1849, was probably the first working chronograph for automatically recording the beats of a clock. A flat disk 22 inches in diameter—made by pasting a dampened sheet of paper over a circular wooden hoop, which dried to become as taut as a drumhead—revolved horizontally once per minute. A make-circuit clock marked every other second with a tiny dot. At the end of every revolution, the disk's position was shifted by 0.07 inch. Two hours of observations were recorded on each flat circular sheet, on which alternate seconds appeared as radial dotted lines and observations as dots irregularly in between.

*Here is the Fauth & Co. Meridian Circle Telescope with an aperture of 5 ¼ inches, a focus of 70 inches, and circles of 11 inches.*

*Here is the Hipp Observatory (slave dial) clock from Peyer Favarger & Co., Neuchatel, Switzerland, that hung on the Fauth & Co. meridian circle telescope in the transit room.*

*These images feature the Hipp Observatory (slave dial) clock working details.*

*This view of the Master clock vault at the Mt. Lookout Observatory shows the outside-wall entrance door, the inside-wall entrance door, and the outside viewing window.*
